

What is claimed is:

1. A method of determining a defect-free or defect semiconductor integrated circuit, comprising:

5 a first measurement step for measuring a quiescent power supply current (QPSC) of a first semiconductor integrated circuit (IC), a plurality of times in a predetermined interval after stop of the operation of the first IC;

10 a first data calculation step for calculating a first feature data indicating a feature(s) of the measured QPSCs of the first IC;

15 a second measurement step for measuring a QPSC of a second semiconductor IC, a plurality of times in the same condition to that of the first IC after stop of the operation of the second IC;

a second data calculation step for calculating a second feature data indicating a feature(s) of the measured QPSCs of the second IC; and

20 a comparison and determination step for comparing a resemble between the first feature data and the second feature data, and determining the first and second ICs as defect-free ICs when the resemble is high or the first and second ICs as defect ICs when the resemble is low.

25 2. A method according to claim 1, wherein the

09064540 092001  
100250 0454960

first and second ICs are formed on the same semiconductor wafer.

3. A method according to claim 2, wherein the IC comprises a complementary metal oxide semiconductor (CMOS) IC.

4. A method according to claim 1, wherein one of the first and second ICs is decided as a reference IC, the second measurement step and the second calculation step are carried out for other semiconductor IC as the second IC,

in the comparison and determination step, the second IC is determined as a defect-free IC when the resemble is high, or as a defect IC when the resemble is low.

5. A method according to claim 1, wherein in the first data calculation step, a first average QPSC of the measured QPSCs of the first IC and a first plurality of QPSC deviations of the measured QPSCs of the first IC which are (the measured QPSCs of the first IC - the first average) are calculated, in the second data calculation step, a second average QPSC of the measured QPSCs of the second IC and a second plurality of QPSC deviations of the measured QPSCs of the second IC which are (the measured QPSCs of the

second IC - the second average) are calculated, and

the method further comprising a third data calculation step for performing a first regression analysis on the first plurality of QPSC deviations and the second plurality of QPSC deviations to produce a first regression line and calculating a gradient of the first regression line, performing a second regression analysis on the measured QPSCs of the first IC to produce a second regression line and calculating a predicted QPSC, and calculating a decision coefficient defined by the following formula, and

$$1 - \frac{\sum (\text{measured QPSCs of the second IC} - \text{predicted QPSC})^2}{\sum (\text{second deviation})^2}$$

wherein, in the comparison and determination step, the first and second ICs are resemble when the decision coefficient is greater than a limit value, and the deviation of the gradient and the ratio is in a predetermined range.

6. A method according to claim 1, wherein in the first data calculation step, a first average QPSC of the measured QPSCs of the first IC, a first standard deviation of the measured QPSCs of the first IC, and first normalized values defined as (the measures QPSCs of the first IC - the first average)/the

108260.0454960  
0964540.092801

first standard deviation are calculated, and

in the second data calculation step, a second average of the measured QPSCs of the second IC, a second standard deviation of the measured QPSCs of the first IC, and second normalized values defined as (the measures QPSCs of the second IC - the second average)/the second standard deviation are calculated,

the method further comprising a third data calculation step for performing a first regression analysis on the first plurality of normalized values and the second plurality of normalized values to produce a first regression line and calculating a gradient of the first regression line, performing a second regression analysis on the first normalized values to produce a second regression line and calculating a predicted normalized value, calculating an average normalized value of the second plurality of normalized values, and calculating a decision coefficient defined by the following formula, and

$$1 - \frac{\sum (\text{second standard values} - \text{predicted standard value})^2}{\sum (\text{second standard values} - \text{average standard value})^2}$$

wherein, in the comparison and determination step, the first and second ICs are resemble when the decision coefficient is greater than a limit value, and

the gradient is in a predetermined range.

7. A method according to claim 1, wherein

in the first data calculation step, a first  
average QPSC of the measured QPSCs of the first IC, a  
first standard deviation of the measured QPSCs of the  
first IC, and a first feature value defined by (the first  
average QPSC / the first standard deviation) are  
calculated,

in the second data calculation step, a second  
average QPSC of the measured QPSCs of the second IC, a  
second standard deviation of the measured QPSCs of the  
second IC, and a second feature value defined by (the  
second average QPSC / the second standard deviation) are  
calculated, and

in the comparison and determination step, the  
first and second ICs are resemble when the first and  
second feature values are in a predetermined range.

8. A method according to claim 1, wherein

in the first data calculation step, a first  
average QPSC of the measured QPSCs of the first IC, first  
QPSC deviations which are (the measured QPSCs of the  
first IC - the first average QPSC), and first feature  
values defined by (the first QPSC deviations / the first  
QPSC average) are calculated,

in the second data calculation step, a second

average QPSC of the measured QPSCs of the second IC,  
second QPSC deviations which are the measured QPSCs of  
the second IC - the second average QPSC, and second  
feature values defined by (the second QPSC deviations /  
5 the second QPSC) are calculated,

in the comparison and determination step, the  
first and second ICs are resemble when the first and  
second feature data are in a predetermined range.

9. A method of determining a defect-free or defect  
10 semiconductor integrated circuit, comprising:

a first measurement step for measuring each  
quiescent power supply current (QPSC) of each of a  
plurality of reference semiconductor integrated circuits  
(ICs), a plurality of times in a predetermined interval  
15 after stop of the operation of the first IC;

a first data calculation step for calculating  
each first QPSC average of measured QPSCs of each  
reference IC, each first standard deviation of the  
measured QPSCs of each reference IC, each of first  
20 normalized values defined by ((the measured QPSCs - the  
corresponding first QPSC average) / the corresponding  
first standard deviation), each of first average  
normalized value of each of first normalized values, each  
of first feature value defined by ((each of the measured  
25 QPSCs - the corresponding each first QPSC average) - (the

corresponding each first normalized values / the  
corresponding each first standard deviation)), and the  
maximum feature value among the first feature values;

5 a second measurement step for measuring a QPSC  
of a test IC a plurality of times in the same conditions  
to the reference ICs after stop of the operation of the  
test IC;

10 a second data calculation step for calculating  
a second QPSC average of measured QPSCs of the test IC, a  
second standard deviation of the measured QPSCs of the  
test IC, second normalized values defined by ((the  
measured QPSCs of the test IC - the second QPSC average)  
/ the second standard deviation), a second average  
normalized value of the second normalized values, and  
15 second feature values defined by ((the measured QPSCs of  
the test IC - the second average QPSC) - (the second  
normalized values / the second standard deviation));

a comparison and determination step for  
comparing the second feature value and the maximum  
20 feature value and determining the test IC as a defect-  
free IC when the second feature values is smaller than  
the maximum feature value or a defect IC when one of the  
second feature values exceeds the maximum feature value.

10. A method of determining a defect-free or defect  
25 semiconductor integrated circuit, comprising:

09260.0454960

5 operation of the reference IC;

a second measurement step for measuring a QPSC of a test IC a plurality of times in the same condition of that of the reference IC after stop of the operation of the test IC;

15 measured QPSCs of the test IC, and

20 defect-free IC when the parameter is smaller than the

semiconductor integrated circuit, comprising:

25

quiescent power supply current (QPSC) of each of a plurality of reference semiconductor integrated circuits (ICs), a plurality of times in a predetermined interval after stop of the operation of the first IC;

5           a first data calculation step for calculating each first QPSC average of measured QPSCs of each reference IC, each first standard deviation of the measured QPSCs of each reference IC, and each of first coefficients defined by ((the measured QPSCs - the  
10   corresponding first QPSC average) / the corresponding first standard deviation);

          a second measurement step for measuring a QPSC of a test IC a plurality of times in the same conditions to the reference ICs after stop of the operation of the  
15   test IC;

          a second data calculation step for calculating a first QPSC average of measured QPSCs of the test IC, and second deviations defined by (the measured QPSCs of the test IC - the first QPSC average);

20           a third data calculation step for performing regression analysis on the first coefficients and the second deviations to produce a regression analysis, calculating a predicted coefficient from the regression line and a gradient of the regression line, and  
25   calculating a decision coefficient by the following

formula, and

$$1 - \frac{\sum (the\ first\ coefficients - the\ predicted\ coefficient)^2}{\sum (the\ second\ deviations)^2}$$

5 a comparison and determination step for  
comparing the test IC as a defect-free IC when the  
decision coefficient is greater than a limit and (the  
gradient / the second deviations) are in a predetermined  
range.

12. A method of determining a defect-free or defect  
10 semiconductor integrated circuit, comprising:

a first measurement step for measuring each  
quiescent power supply current (QPSC) of each of a  
plurality of reference semiconductor integrated circuits  
(ICs), a plurality of times in a predetermined interval  
15 after stop of the operation of the first IC;

a first data calculation step for calculating  
each first QPSC average of measured QPSCs of each  
reference IC, each first standard deviation of the  
measured QPSCs of each reference IC, each of first  
20 normalized values defined by ((the measured QPSCs - the  
corresponding first QPSC average) / the corresponding  
first standard deviation), each of first average  
normalized value of each of first normalized values, and  
each of first feature value defined by ((each of the

measured QPSCs - the corresponding each first QPSC average) - (the corresponding each first normalized values / the corresponding each first standard deviation));

5 a second measurement step for measuring a QPSC of a test IC a plurality of times in the same conditions to the reference ICs after stop of the operation of the test IC;

10 a second data calculation step for calculating a second QPSC average of measured QPSCs of the test IC, a second standard deviation of the measured QPSCs of the test IC, second normalized values defined by ((the measured QPSCs of the test IC - the second QPSC average) / the second standard deviation)), and second normalized  
15 value deviation defined as (the second normalized values - the average normalized values);

a third data calculation step for performing regression analysis on the first coefficients and the second deviations to produce a regression analysis,  
20 calculating a predicted feature value from the regression line and a gradient of the regression line, and calculating a decision coefficient by the following formula, and

$$1 - \frac{\sum (the\ first\ feature\ values - the\ predicted\ feature\ value)^2}{\sum (the\ second\ standard\ values - an\ average\ of\ the\ second\ standard\ value)^2}$$

09664540 092801 108260 04549660

a comparison and determination step for determining the test IC as a defect-free IC when the decision coefficient is greater than a limit and the gradient is in a predetermined range.

- 5 13. An apparatus for determining a defect-free or defect semiconductor integrated circuit, comprising:

0961510 092901  
100260 0451960

a first measurement means for measuring a quiescent power supply current (QPSC) of a first semiconductor integrated circuit (IC), a plurality of times in a predetermined interval after stop of the operation of the first IC;

a first data calculation means for calculating a first feature data indicating a feature(s) of the measured QPSCs of the first IC;

- 15 a second measurement means for measuring a QPSC of a second semiconductor IC, a plurality of times in the same condition to that of the first IC after stop of the operation of the second IC;

a second data calculation means for calculating a second feature data indicating a feature(s) of the measured QPSCs of the second IC; and

- a comparison and determination means for comparing a resemble between the first feature data and the second feature data, and determining the first and second ICs as defect-free ICs when the resemble is high
- 20 25

or the first and second ICs as defect ICs when the resemble is low.

14. An apparatus according to claim 13, wherein the first and second ICs are formed on the same semiconductor  
5 wafer.

15. An apparatus according to claim 14, wherein the IC comprises a complementary metal oxide semiconductor (CMOS) IC.

16. An apparatus according to claim 13, wherein  
10 one of the first and second ICs is decided as a reference IC,

the second measurement means and the second calculation means operate for other semiconductor IC as the second IC,

15 the comparison and determination means determines the second IC as a defect-free IC when the resemble is high, or as a defect IC when the resemble is low.

17. An apparatus according to claim 13, wherein  
20 the first data calculation means calculates a first average QPSC of the measured QPSCs of the first IC and a first plurality of QPSC deviations of the measured QPSCs of the first IC which are defined (the measured QPSCs of the first IC - the first average), and

25 the second data calculation means calculates a

second average QPSC of the measured QPSCs of the second IC and second plurality of QPSC deviations of the measured QPSCs of the second IC which are defined as (the measured QPSCs of the second IC - the second average),

5 the apparatus further comprising a third data calculation means for performing a first regression analysis on the first plurality of QPSC deviations and the second plurality of QPSC deviations to produce a first regression line and calculating a gradient of the first regression line, performing a second regression analysis on the measured QPSCs of the first IC to produce a second regression line and calculating a predicted QPSC, and calculating a decision coefficient defined by the following formula, and

15 
$$1 - \frac{\sum (\text{measured QPSCs of the second IC} - \text{predicted QPSC})^2}{\sum (\text{second deviation})^2}$$

wherein, the comparison and determination means comprises the first and second ICs and decides the both resemble when the decision coefficient is greater than a limit value, and the deviation of the gradient and the ratio is in a predetermined range.

18. An apparatus according to claim 13, wherein the first data calculation means calculates a first average QPSC of the measured QPSCs of the first IC,

a first standard deviation of the measured QPSCs of the first IC, and first normalized values defined as (the measures QPSCs of the first IC - the first average)/the first standard deviation, and

5           the second data calculation means calculates a second average of the measured QPSCs of the second IC, a second standard deviation of the measured QPSCs of the first IC, and second normalized values defined as (the measures QPSCs of the second IC - the second average)/the  
10   second standard deviation,

          the apparatus further comprising a third data calculation means for performing a first regression analysis on the first plurality of normalized values and the second plurality of normalized values to produce a  
15   first regression line and calculating a gradient of the first regression line, performing a second regression analysis on the first normalized values to produce a second regression line and calculating a predicted normalized value, calculating an average normalized value  
20   of the second plurality of normalized values, and calculating a decision coefficient defined by the following formula, and

$$1 - \frac{\sum (\text{second standard values} - \text{predicted standard value})^2}{\sum (\text{second standard values} - \text{average standard value})^2}$$

wherein, the comparison and determination means compares the first and second ICs and decides the both resemble when the decision coefficient is greater than a limit value, and the gradient is in a predetermined range.

19. An apparatus according to claim 13, wherein the first data calculation means calculates a first average QPSC of the measured QPSCs of the first IC, a first standard deviation of the measured QPSCs of the first IC, and a first feature value defined by (the first average QPSC / the first standard deviation),

the second data calculation means calculates a second average QPSC of the measured QPSCs of the second IC, a second standard deviation of the measured QPSCs of the second IC, and a second feature value defined by (the second average QPSC / the second standard deviation), and

the comparison and determination means compares the first and second ICs and decides the both resemble when the first and second feature values are in a predetermined range.

20. An apparatus according to claim 13, wherein the first data calculation means calculates a first average QPSC of the measured QPSCs of the first IC, first QPSC deviations which are (the measured QPSCs of the first IC - the first average QPSC), and first feature

values defined by (the first QPSC deviations / the first QPSC average),

the second data calculation means calculates a second average QPSC of the measured QPSCs of the second IC, second QPSC deviations which are the measured QPSCs of the second IC - the second average QPSC, and second feature values defined by (the second QPSC deviations / the second QPSC), and

the comparison and determination means compares the first and second ICs and decides the both resemble when the first and second feature data are in a predetermined range.

21. An apparatus for determining a defect-free or defect semiconductor integrated circuit, comprising:

a first measurement means for measuring each quiescent power supply current (QPSC) of each of a plurality of reference semiconductor integrated circuits (ICs), a plurality of times in a predetermined interval after stop of the operation of the first IC;

a first data calculation means for calculating each first QPSC average of measured QPSCs of each reference IC, each first standard deviation of the measured QPSCs of each reference IC, each of first normalized values defined by ((the measured QPSCs - the corresponding first QPSC average) / the corresponding

09964540-092801

5

10

15

20

25

the maximum feature value or a defect IC when one of the second feature values exceeds the maximum feature value.

22. An apparatus for determining a defect-free or defect semiconductor integrated circuit, comprising:

- 5           a first measurement means for measuring a quiescent power supply current (QPSC) of a reference semiconductor integrated circuit (IC), a plurality of times in a predetermined interval after stop of the operation of the reference IC;
- 10           a first data calculation means for calculating a first standard deviation of measured QPSCs of the reference IC;
- a second measurement means for measuring a QPSC of a test IC a plurality of times in the same condition
- 15           of that of the reference IC after stop of the operation of the test IC;
- a second data calculation means for calculating a QPSC average and a second standard deviation of measured QPSCs of the test IC, and
- 20           a comparison and determination means for comparing a parameter which is ((QPSC average - (the second standard deviation / the first standard deviation)) and a limit and determining the test IC as a defect-free IC when the parameter is smaller than the
- 25           limit or the test IC as a defect IC when the parameter is

100250-0757969

equal or greater than the limit.

23. An apparatus for determining a defect-free or defect semiconductor integrated circuit, comprising:

5 a first measurement means for measuring each quiescent power supply current (QPSC) of each of a plurality of reference semiconductor integrated circuits (ICs), a plurality of times in a predetermined interval after stop of the operation of the first IC;

10 a first data calculation means for calculating each first QPSC average of measured QPSCs of each reference IC, each first standard deviation of the measured QPSCs of each reference IC, and each of first coefficients defined by ((the measured QPSCs - the corresponding first QPSC average) / the corresponding  
15 first standard deviation);

a second measurement means for measuring a QPSC of a test IC a plurality of times in the same conditions to the reference ICs after stop of the operation of the test IC;

20 a second data calculation means for calculating a first QPSC average of measured QPSCs of the test IC, and second deviations defined by (the measured QPSCs of the test IC - the first QPSC average);

25 a third data calculation means for performing regression analysis on the first coefficients and the

5 formula, and

10 decision coefficient is greater than a limit and (the  
gradient / the second deviations) are in a predetermined  
range.

15                    a first measurement means for measuring each  
quiescent power supply current (QPSC) of each of a  
plurality of reference semiconductor integrated circuits  
(ICs), a plurality of times in a predetermined interval  
after stop of the operation of the first IC;

20           a first data calculation means for calculating  
each first QPSC average of measured QPSCs of each  
reference IC, each first standard deviation of the  
measured QPSCs of each reference IC, each of first  
normalized values defined by ((the measured QPSCs - the

5

10
